Abstract— Approximately 90% of freshwater on the earth surface is stored by lakes and reservoirs that provide benefits for human life such as for daily water needed, industry, agriculture, transportation, hydroelectric power and tourism. Most watersheds (DAS) and lakes in Indonesia have experienced the quality and quantity degradation caused by population growth, land conversion and erosion. Lake Rawapening in Central Java is one of fifteen Indonesian National Priority Lakes that should be seriously monitored and well managed. For routine monitoring of land cover change of the lake and its watershed, an optical remote sensing data that generally used was facing a problem related to cloud cover over the area of lake. In this research, we propose the utilization of Sentinel 1A, an active RADAR remote sensing data which can penetrate the cloud, thus more effective for observing land cover changes. The classification result of December 2016 data has strong relationship with field object (Kappa= 94.218%). All water objects were recognized as water, 94.595% of wetland were recognized as wetland (others as water), 91.379% of vegetation were recognized as vegetation (others as agriculture), 95.238% of agriculture were recognized as agriculture (others as urban) and 96.774% of urban were recognized as urban (others as wetland and agriculture). During May and December 2016, the landcover change was triggered by high precipitation in December and rapid-uncontrolled growth of water hyacinth in May. During May and December 2016, the landcover change was triggered by high precipitation in December and rapid-uncontrolled growth of water hyacinth in May.

Keywords—Lake Ecosystem Monitoring, Satellite Data, Active Remote Sensing

I. INTRODUCTION

Lakes play important roles as freshwater resources for drinking water, agriculture, industry, fishing, recreation, and tourism [1]. Most of fresh water on the earth surface is stored by lakes and reservoirs that provide benefits for human life. Based on a report released by the Ministry of Environment (KLH) of Indonesia , watersheds and lakes ecosystems in Indonesia contain 25% of the world's germplasm, supplying 72% of surface water and water providers for agriculture, community water resources, agriculture, hydroelectric power, tourism and others[2]

Water catchment area of lake needs to have at least 30% of forest area with controlled erosion and sediment rate. However, most of lakes in Indonesia are suffering from several damages that needs to be saved[3]. The decrease of lake quality is mainly caused by population growth, pollution, erosion and land conversion. The conversion of forests in the area around lake into residential areas, plantations, agriculture, recreation and road infrastructure will cause soil erosion during the rainy season and reduce the catchment area. This condition will change a lake as an aquatic ecosystem to the form of the terrestrial ecosystem [4].

Based on the National Conference of Lake in Indonesia hold in 2009, there are 15 lakes priorities that increasingly threatened due to damage and environmental pollution in water catchment area. Lake Toba, Lake Maninjau, Lake Singkarak, Lake Sentani, Rawa Lake, Lake Batur, and Lake Rawa Pening, Lake Toba, Lake Matano and Lake Mahakam (Semayang, Jempang, Melintang) was listed as lakes priorities [3].

Lake Rawapening is one of lake priorities located in Central Java. Lake Rawapening plays as a source of life for local community indicated by their various daily activities are conducted in Lake Rawapening and its watershed[5]. The degradation of lake function was triggered by land conversion at water catchment area into settlement and agriculture field especially in Kebumen, Tegaron and Sepakung.

Figure 1. Study Area: Lake Rawapening

According to the Ministry of Environment report in 2010, Lake Rawapening has undergone many ecologically changes that can be seen from uncontrolled water weeds, even in the dry season it can cover the surface of the lake up to 70% and decrease lake water volume by 29.34% over a period of 22 Year (1976 - 1998). The presence of water hyacinth or weeds in large quantities that covered the surface of waters will reduce the light penetration into water, reduce oxygen dissolved in water, then reduce aquatic animals. This also has negative effects to fishermen income [6]. If the amount of water hyacinth couldnot be controlled, it is estimated that by 2021 water ecosystem in Lake Rawapening will be totally transformed into a land ecosystem [7].

In order to monitor the land cover change over Lake Ecosystem, an efficient method such as remote sensing technique can be utilized. To reduce the cloud cover disruption encountered when using optical satellite imagery, the Synthetic Aperture Radar (SAR) data can be utilized. This SAR data can penetrate the cloud, then more effective to observe land cover change in the tropical region [8].

The European Space Agency (ESA) launched one of the constellation of two radar satellite Sentinel-1A in April 2014. Sentinel satellite provides C-band images in both singular and dual polarization within 12 days of repeated cycle. The data is free of charge for all users which makes it more attractive for new challenging applications and opportunities [9]. It can acquires images in three acquisition modes as Stripmap (SM), Interferometric Wide Swath (IW), Extra Wide Swath (EW) and Wave (WV) with different processing levels [10].

In this research We evaluate the land cover changes of Lake Rawapening area using Sentinel-1A Level-1 Ground Range Detected High-resolution (GRDH) products acuired on May 8, 2016 and December 10, 2016

II. METHOD

A. Data

In this research, 4 Sentinel-1 data recorded in 2015 and 2016 were used. The data was grouped into two different sessions as presented in Table 1.

Table 1. Data

No	ID_Scene	Acquisition Date	Season
1	S1A_IW_GRDH_1SDV _20150514T221659_201 50514T221735_005923_0 07A15_D752	14 May 2015	dry

B. Pre-processing

Pre-processing Sentinel-1 (Level 1, GRDH) data was performed using Sentinel-1 Toolbox (S1Tbx) software. The initial process involved applying orbit correction to update the orbital file in the metadata, to provide accurate position and satellite speed. Then, radiometric calibration was performed to produce sigma nought value (σ°). In order to reduce the speckle effect of SAR image, a speckle filtering with 5×5 gamma map was done. If Sentinel-1A image was in reverse position, then geometric distortion need to be corrected by applying an geometric correction with Doppler Range Terrain Correction. The Digital Number (DN) value of the SAR data was converted to the backscatter value in decibels (db). Some of these corrections were useful for reducing topographic effects but resulting a different slope correction effects. Here, the slope correction model from Kellndorfer et. al. was used to correct the slope effects (1998) [11]

$$\sigma_c^{\circ} = \sigma^{\circ} \frac{\sin \varphi}{\sin \theta} \tag{1}$$

 σ_c° is backscatter coefficient of SAR after calibration, σ° is original backscatter coefficient of SAR, φ is Local Incidence Angle, and θ is SAR Incidence Angle at the center of image [12]. Digital Number (DN) data was converted into backscatter in decibel (db). After slope normalization, a vector data was used to subset area of study. All of data then exported into KMZ format to overlaid in Google Earth.

C. Image Classification

For image classification, a Semi-Automatic Classification Plugin (SCP) on QGIS software was used. This plugin provides some tools for classification processing and raster calculation. SAR data was analyzed based on RGB color system, where VV, VH and VV/VH assigned as Red, Green and Blue, respectively.

D. Accuracy assessment

Accuracy assessment was performed for classified image and 'field' object using following kappa coefficient formula [13]

$$Kappa(k) = \frac{N\sum_{i}^{r} X_{ii} - \sum_{i}^{r} X_{i+} X_{+i}}{N^{2} - \sum_{i}^{r} X_{i+} X_{+i}} \times 100\%$$
(2)

K is Kappa Coefficient, $\sum_{i=1}^{I} \pi_{ii}$ is the total proportion of main diagonal of observation frequency and $\sum_{i=1}^{I} \pi_{i+}\pi_{+i}$ is total major marginal proportion of observation frequency. Kappa analysis tool follows the rule of Kappa <0.20 as low correlation; 0.21-0.40 is Fair; 0.41-0.60 is enough, 0.61-0.80 is strong and 0.81 – 1.00 is very strong [14] Regional Conference in Civil Engineering (RCCE) The Third International Conference on Civil Engineering Research (ICCER) August 1st-2nd 2017, Surabaya – Indonesia

E. Area Calculation

After performing the accuracy assessment, the final step was to calculate the area of each object class to analyze the land cover change within the time range of May 2016 and December 2016.

III. RESULTS AND DISCUSSION

Sentinel-1A with polarization of VV, VH, and VV / VH have been classified into 5 classes ie water, wetlands, agriculture, vegetation and urban. The classification result was presented in Figure 2. Accuracy of classification results with supervised methods produced overall accuracy of 96.417% and Kappa accuracy of 0.954. The kappa accuracy was in the range of strong correlation between classified object and field object.

Figure 2. Landcover classification: 14 May 2015 (top) 16 December 2015 (bottom)

Figure 3. Landcover classification: 8 May 2016 (top) 10 December 2016 (bottom)

Class	Area (ha) 2015		Area (ha) 2016		
Class	May	December	May	December	
Water	903.449	341.427	650.199	437.495	
Agriculture	5947.993	2281.351	5878.058	2252.789	
Wetlands	511.777	845.290	313.889	409.849	
Vegetation	16783.044	20675.005	17299.961	21040.292	

Regional Conference in Civil Engineering (RCCE) The Third International Conference on Civil Engineering Research (ICCER) August 1st-2nd 2017, Surabaya – Indonesia

Urban	3358.285	3361.475	3362.441	3364.123
Total	27504.548	27504.548	27504.548	27544.548

After accuracy assessment, the area of each class of each classified sentinel data was calculated. The area of classified data was dominated by vegetation class following by urban, agriculture, water and wetland. As presented in Table 2 the largest water area occurred in May 2015 (903.449 ha) and May 2016 (650.199 ha) compared to in December 2015 and December 2016. This was because during May 2015 and 2016 before Sentinel-1A SAR data was recorded, there were routine activities of cleaning water plants in Rawapening lake by local people.

Table 3. Confussion Matrix of Sentinel 1A Classification

Classification	Reference				No. of Row	User's Accuracy (%)	
	Α	В	С	D	E		
А	41	0	0	0	0	41	100.00
В	0	40	0	2	0	42	95.238
С	2	0	35	0	0	37	94.595
D	2	3	0	53	0	58	91.379
E	0	2	0	0	60	62	96.774
No. of	45	45	35	55	60	240	
Column							
Kappa (k) = 94.218%							
Overall accuracy = 95.417%							

A, B, C, D, E is water, agriculture, wet land, vegetation and urban areas, respectively.

The convolution matrix was presented to analyzed the accuracy of each class of classification. As presented in Table 3, all data was classified into 5 classes: water, wetland, vegetation, agriculture and urban. In the data of December 2016, there was 100% of water object which recognized as water, 94.595% of wetland were recognized as wetland (others as water), 91.379% of vegetation were recognized as vegetation (others as agriculture), 95.238% of agriculture were recognized as agriculture (others as urban) and 96.774% of urban were recognized as urban (others as wetland and agriculture).

The area of agriculture decreased by 3666.642 ha in December 2015 and by 3625.269 ha in December 2016. This phenomenon occurred because of agriculture area often flooded during the rainy season. This was also accompanied by the increasing of wetlands area during the rainy season about 333.513 ha in 2015 and 95.960 ha in 2016.

Vegetation area in rainy season (December) was 3891.961 ha and 3740.331 ha larger than in dry season (May) of 2015 and 2016. Meanwhile, urban area around the lake Rawapening continuously increased of 3.190 ha from May 2015 to December 2015, 0.966 ha from December 2015 to May 2016 and 1.682 ha in the period of May 2016 to December 2016.

IV. CONCLUSION

We have processed remotely sensed data acquired by Sentinel 1 SAR sensor for land cover monitoring in Lake Rawapening and its watershed area. The classification result of December 2016 data has strong relationship with field object (Kappa= 94.218%). All water objects were recognized as water, 94.595% of wetland were recognized as wetland (others as water), 91.379% of vegetation were recognized as vegetation (others as agriculture), 95.238% of agriculture were recognized as agriculture (others as urban) and 96.774% of urban were recognized as urban (others as wetland and agriculture). During May and December 2016, the landcover change was triggered by high precipitation in December and a rapid-uncontrolled growth of water hyacinth in May.

V. ACKNOWLEDGEMENT

We thank to the Center for Earth, Disaster and Climate Change (PSKBPI) of Institut Teknologi Sepuluh Nopember for data support and guidance during this research.
